

There are two output:

— a jack with no ground connection for internal use within the synthesizer (all modules are internally connected to ground by means of their connection to the power supply).

— an audio jack with a signal and ground wire for connections to external devices. The mixer has an audio output jack because it's likely the final element in most signal chains constructed with the synthesizer. Additionally it's probably safer for external signals to be centred about it's probably safer for external signals to be centred about it. it's probably safer for external signals to be centred about OV and the mixer happens to center its input signals about OV as part of its regular operation, so it's a good opportunity to allow an external device to connect.
